TECHNICAL MEMORANDUM 2 ADDENDUM TO FINAL PHASE II RFI/RI WORK PLANS (ALLUVIAL AND BEDROCK) CHEMICAL ANALYSIS PLAN 903 PAD, MOUND, AND EAST TRENCHES AREAS (OPERABLE UNIT NO. 2)

This document provides analysis and rationale for amending the analytical strategy for the Resource Conservation and Recovery Act (RCRA) Facility investigation/Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) Remedial Investigation (RFI/RI) (Alluvial and Bedrock) at Operable Unit No 2 (OU2) The RFI/RI Work Plans stipulates that soils, sediments, ground water, and surface water be analyzed for all Contract Laboratory Program (CLP) Target Compound List (TCL) organic constituents. This analytical program is conservative for various reasons discussed herein, however, considering that the RFI/RI for OU2 is in its second phase, it appears that the need for such a comprehensive analytical program should be reevaluated. This document presents a historical review of how the analyte lists evolved as well as an analysis of available sampling results from OU2 as justification for eliminating certain analytical suites from the overall program. The basis for developing a site-specific target analyte list is discussed in U.S. Environmental Protection Agency (EPA) guidance documents for conducting remedial investigations and feasibility studies (EPA, 1988) and for developing data quality objectives for remedial response activities (EPA, 1989). As discussed with EPA and the Colorado Department of Health (CDH) in a meeting on 17 May 1991, the approach is applicable to establishing the analytical strategy for the upcoming OU2 RFI/RI

BACKGROUND

Comprehensive site characterization began at OU2 in 1986, and a Phase I RI report for OU2 was submitted in December 1987. Site characterization for this previous RI was based on analysis of soils, sediments, ground water and surface water for the CLP Hazardous Substance List (HSL) compounds (Currently this list of analytes is known as the TCL, however, it should be noted that there are minor differences in the two lists.) Phase II RFI/RI Work Plans for the alluvial and bedrock hydrogeologic systems have been prepared for OU2 which are designed to fill data gaps that were identified in the earlier phase of investigation

The OU2 RFI/RI Work Plans specify analysis of soils, sediments, ground water, and surface water for all TCL organic compounds. Analysis for the full suite of TCL organics for ground water and surface water beyond the first round of samples would be dependent on the initial results. The need for continued full suite analysis would be based on an assessment approach not unlike that presented in this document. The TCL was chosen as the basis for characterizing this OU because it is used by EPA in characterizing uncontrolled hazardous waste sites where historical waste disposal practices are often unknown, and because of the

Technical Memorandum 2 903 Pad Mound, and East Trenches Areas Revision 1 eg&g/wp-adden\ou2-bt.sep September 1991

Page 1

12 Marks

associated high quality assurance/quality control procedures that are widely accepted by both federal and state agencies. Although chlorinated solvents (and radionuclides) are the principal contaminants at this OU, based on historical waste disposal records and previously collected data, a list of all chemicals disposed at this location is not known, which established the need for monitoring for a more comprehensive list of analytes

With respect to soils, the full suite of TCL organics was specified, because the upcoming phase of investigation is designed to provide a comprehensive characterization eliminating the need for subsequent phases of investigation. More specifically, semivolatiles and pesticides/polychlorinated biphenyls (PCBs) were to be analyzed at OU2 because previously collected data indicated the consistent occurrence of phthalate esters and the infrequent occurrence of other semivolatile compounds and pesticides/PCBs. Also, several proposed waste investigation boreholes will penetrate waste sources (Individual Hazardous Substance Sites [IHSSs]), where previous targeted soil sampling was outside the waste source boundaries. Thus, the full suite of TCL organics is currently specified because of the uncertainty of the types of waste that were disposed at these OU2 IHSSs

Ground water and surface water were to be analyzed for the full suite of TCL organics because of the infrequent occurrence of semivolatiles and pesticides/PCBs as indicated by previously collected data, and the ilmited quantity of historical data for these classes of chemicals (one to two rounds). Sediments were also to be analyzed for the full suite of TCL organics largely because of it's relevance to contaminant migration in surface water.

APPROACH

The approach to defining a site-specific target analyte list consists of the following two steps

Step 1 Summarize Existing Analytical Data by Analytical Suite

In step 1, existing data are tabularized showing the total number of analyses for each chemical within an analytical suite, and the total number of detections of each chemical. This is performed for each medium that was characterized. Seven analytical suites within three major chemical groupings based on analytical protocol can be identified. The analytical suites are as follows.

Group A Compounds, TCL Volatiles

i Ketones and Aldehydes

II Monocyclic Aromatics

III Chlorinated Aliphatics

Group B Compounds, TCL Semivolatiles

IV Acid Extractables

V Base Neutral Extractables

Group C Compounds, Pesticides/PCBs

VI Pesticides

VII PCBs

This exercise yields one of three possible outcomes

- 1) Case 1: Chemicals within one or more analytical suites in a specified media have not been detected above the Contract Required Quantitation Limit (CRQL)
- 2) Case 2 One or more chemicals from an analytical suite have been detected in a specified media either inconsistently or at low concentrations.
- 3) Case 3: Consistent detections of one or more chemicals from an analytical suite in a specified media.

Step 2 Evaluation of Results

Each of the cases identified above have implications with regard to the elimination of an analytical suite from the analytical program. In Case 1, a strong case can be made to eliminate the analytical suite provided the historical data are of adequate quality or useability, and are representative of the site. Data quality is assessed in accordance with the Environmental Restoration (ER) Program Quality Assurance Project Plan (QAPjP) and the General Radiochemistry and Analytical Services Protocol (GRAASP), and references therein Evaluation of representativeness must include spatial considerations. For example, if the chemicals within one or more analytical suites were not detected at a specified sample location, it is necessary to be sure associated potential waste sources were investigated. Elimination of a suite of chemicals, where historical data fit Case 2, requires an assessment of data quality, spatial representativeness, temporal considerations (depending on the concentrations observed), chemical fate and transport, and human risks posed by the chemicals. For Case 3, continued monitoring for the analytical suite(s) in order to better characterize the medium is justified, particularly if the chemicals are mobile and toxic

Assessment of chemical fate and transport and human/environmental risks is one of determining whether the chemical is at a concentration in a specific medium that poses an unacceptable risk to humans or the environment through a likely exposure pathway, and whether the chemical can migrate to another medium at concentrations that also pose an unacceptable risk

Fate and Transport

Table 1 presents some of the relevant chemical/physical parameters that relate to the environmental fate and transport of representative chemicals from each of the analytical suites previously identified. The general tendency for chemicals from each group to migrate from one environmental medium to another is discussed below. This is summarized in Table 2.

Group A Compounds, TCL Volatile Organic Compounds

Generally, TCL volatile organic compounds (VOCs) have computed mobility indices that suggest high mobility in the environment. They are characterized by relatively high water solubility (greater that 100 milligrams per liter [mg/l]) and volatility (vapor pressures generally much greater than 1 millimeter (mm) mercury (Hg) and Henry's Law Constants greater than 0 1) Volatiles can be expected to migrate through soils, and to be transported by ground water and surface water as neutral solutes. This is denoted by the saturated zone retardation factors (Rds) generally between 1 and 50 (Note chemical migration velocity = water migration velocity/Rd) The substantial vapor pressures and Henry's Law Constants suggest a tendency to volatilize from aqueous systems (including soil water) to the atmosphere

Group B and C Compounds, Semivolatiles and Pesticides/PCBs

In general, semivolatiles and pesticides/PCBs are considered to be slightly to very immobile (pesticides and PCBs are particularly immobile). Again this is denoted by the high Rds. Phenois are the most mobile of these compounds owing to their high water solubility. Semivolatiles and pesticides/PCBs exhibit low to negligible volatility as indicated by the very low vapor pressures and Henry's Law Constants. This suggests a low propensity for volatilization of these compounds to the atmosphere from soil and soil water.

Toxicity

Without the benefit of a risk assessment, it is necessary to rely on published acceptable concentrations for chemicals to estimate the risk posed by the various chemicals in each of the media they are found. Many of these published standards are considered Applicable or Relevant and Appropriate Requirements (ARARs). In this analysis, Safe Drinking Water Act (SDWA) Maximum Contaminant Levels (MCLs) (an ARAR) and Action Levels under EPA's proposed RCRA Corrective Action Regulations (FR v 55, No. 145, July 27, 1990, 40 CFR 264 521) are used to provide an estimate of concentrations of chemicals that are protective of human health. The Action Levels are based on likely chemical exposure scenarios, a 10-6 incremental cancer risk (for carcinogens), or a no-adverse health effect from a lifetime of exposure to a systemic contaminant (non carcinogen). MCLs and Action Levels used in this assessment are shown in Table 3.

Technical Memorandum 2 903 Pad, Mound, and East Trenches Areas Revision 1 eg&g/wp-adden/ou2-bd.sep

FINDINGS

Data Considered in This Evaluation

Data from OU2 contained in the Rocky Flats Environmental Database System (RFEDS) were used to perform this evaluation. Data from the boreholes, ground-water wells, surface water stations, and sediment stations listed in Table 4 and shown in Figures 1 and 2 have been summarized in this document. This includes all existing soil/sediment data and surface water and ground-water data collected through March of 1991 Table 5 identifies the boreholes in the proximity of each IHSS. Table 6 lists ground-water monitoring wells and surface water stations that may be impacted by each IHSS.

Data Quality, Useability, and Representativeness

With the exception of the cases discussed below, soil and water quality data are either valid or acceptable with qualifications, based on limited data validation conducted in accordance with guidance provided in the ER QAPjP and GRAASP. With respect to both soils and ground water, high concentrations of acetone, butanone, and methylene chloride in the laboratory blanks for the 1986 and 1987 investigations render it difficult to ascertain their presence in samples as an indication of site contamination. Furthermore, volatile organic data for soils was rejected principally because of the high dilutions used (high detection limits). Since the 1986 and 1987 investigations, the sample collection methodology for VOCs in soils has been significantly improved to prevent volatile release during sample handling. Therefore, these soil data have little or no useability. In contrast, semivolatile and pesticide/PCB analyses of soils are valid or acceptable with qualifications based on the limited data validation.

With respect to representativeness, the previous results are from boreholes, ground-water monitor wells and surface water/sediment stations that span the entire OU. However, boreholes at OU2 did not penetrate all the IHSSs. Therefore, previous soil data cannot always be considered representative of buried wastes characteristics for all IHSSs. Also, ground-water and surface water semivolatile and pesticide/PCB data are based on limited rounds of sampling. The impact of these observations are discussed in the following section.

Results

Table 7 provides a tabulation of the total number of analyses for each analytical suite and the number of occurrences for which a chemical was detected. A detection is defined as all reported concentrations of a chemical above the CRQL, and chemical concentrations estimated below the detection limit ("J" qualifier). As indicated in Table 7 and discussed further in subsequent sections, VOCs are a class of contaminants that are pervasive in all environmental media at OU2. VOCs represent the Case 3 scenario. In contrast, the other

we also see make

Technical Memorandum 2 903 Pad Mound and East Trenches Areas Revision 1 eg&g/wp-adden/ou2-bt sep analytical suites occur much less frequently (Case 2) and are the primary subject of this technical memorandum Table 8, 9, and 10 summarize, by IHSS, the occurrence of these non-volatile organics

Ground Water and Surface Water

Voiatile Organic Compounds

As shown in Tables 11, 12, and 13, VOCs are frequently detected and in significant concentrations. The chlorinated aliphatics occur often and occasionally at high concentrations. These compounds are known waste constituents and are relatively toxic. Acetone, and to a lesser extent other ketones, also appear in the samples. However, the occurrence of acetone and 2-butanone in a sample is often due to laboratory contamination, and there are no occurrences of acetone or 2-butanone above their action levels. Concentrations of these ketones are generally two orders of magnitude less than the action level. Based on the high health-based reference concentrations (action levels) of acetone and 2-butanone, it can be surmised that ketones are relatively non-toxic, and the less frequent occurrence of other ketones at low concentrations is of little concern. Therefore, ketones could be eliminated from future analysis at OU2. However, there is little advantage in removing the ketones from the TCL volatile suite, and, therefore, ground-water and surface water samples will be analyzed for all TCL VOCs. As a class, the VOCs represent Case 3.

Semivolatiles (acid extractables)

As shown in Tables 14, 15 and 16, out of 93 analyses for acid extractables in ground and surface water, there have been a total of nine detections of 2-methylphenol, benzolc acid, benzyl alcohol, pentachlorophenol, and phenol within this analytical suite. Acid extractables were not detected in bedrock ground water. Two of the four detections of phenoi are at concentrations of 13 micrograms per liter ($\mu g/t$) and 15 $\mu g/t$, and occurred at station SW-27, and Pond C-2, respectively (Table 17) The other two detections of phenol are for Pond C-2 but occurred at estimated concentrations (2J μ g/t and 9J μ g/t) below the detection limit. The action level for phenol in water is 20,000 μ g/2 Although phenol occurred in the sediments at SED030 (650J µq/kilogram [kg]) (See Table 28), immediately upstream of SW-27, it did not occur in sediments in the associated sediment station (SED025), nor did it occur in surface water immediately upstream, or in soils or ground water anywhere within OU2. The occurrences of phenol at stations SW-27 and Pond C-2 are at low concentrations, and were not detected in three other samplings of water at station SW-27 or in ten other sampling events at Pond C-2 The occurrence of 2-methylphenol (24 μ g/t) and benzoic acid (8J μ g/t) at station SW-27 were at low concentrations and not detected in three other subsequent water sampling events at the station (Table 17) Benzoic acid was detected once at station SW-64 (8J μ g/ ℓ) at an estimated concentration below the detection limit and did not occur in sediments, soils, or ground water anywhere within OU2 Similar to benzoic acid, benzyl alcohol occurred once at station SW-65 (4J $\mu g/l$), and was not detected

Technical Memorandum 2 903 Pad Mound and East Trenchee Areas Revision 1 eg&g/wp-adden/ou2-bt.sep

in two other water sampling events at this station or in any other medium at OU2. The only detection of an acid extractable compound in ground water is pentachlorophenol (4J μ g/t) at well 39-86, approximately 3,000 feet northeast of the East Trenches Area. Although pentachlorophenol was detected in the soils (at the bedrock contact and water table in boreholes BH4787 and BH5487, respectively) (See Table 30), it was not detected in ground water immediately downgradient (well 41-86). Furthermore, the pentachlorophenol Rd (Table 1) together with the average seepage velocity of 82 feet per year (ft/yr) suggests the compound would have migrated less than 1 foot from this location during the past 30 years. This suggests the datum for well 39-86 is spurious. Regardless, the health-based reference concentration for pentachlorophenol is 1,000 μ g/t

Although acid extractables in ground and surface waters may have arisen from Trenches T-5 through T-8 (Table 8) based on hydraulic gradients and topographic grades, respectively, the above stated arguments and the fact that there is no history of disposal of wastes containing acid extractable compounds, strongly justifies elimination of this analytical suite from future water monitoring at OU2

Semivolatiles (base neutral extractables)

As shown in Tables 18, 19, and 20, base/neutral extractables rarely occur in water at OU2. The most frequently occurring compounds are phthalate esters, particularly bis(2-ethylhexyl) phthalate and di-n-buthyl phthalate, at estimated concentrations below the detection limit, and near the action level of $3 \mu g/l$. However, bis(2-ethylhexyl) phthalate did occur at 220 $\mu g/l$ at SW-27, but is considered an outlier relative to the concentrations observed elsewhere and the fact that it was not detected at this station during three other samplings. Phthalate esters are common laboratory contaminants, and bis(2-ethylhexyl) phthalate and di-n-butyl phthalate often occurred in laboratory blanks for the samples where this compound was detected ("B" qualifier)

N-nitrosodiphenylamine occurred second most frequently, however, this compound is also a known laboratory contaminant that leaches from the gas chromatograph column. (Note the compound occurred in the laboratory blank in more than haif the samples.) This compound did occur at 200 μ g/ ℓ in Pond C-2, but is also considered an outlier relative to other concentrations observed and the fact that it was not detected in 22 other samplings at this station. The remaining detections of N-nitrosodiphenylamine are near the health-based reference concentration (7 μ g/ ℓ), and are at estimated concentrations below the detection limit and/or also occurred in the laboratory blank

The remaining few base neutral extractable compounds that were detected are polynuclear aromatic hydrocarbons (PNAs) and all occurred at surface water station SW-101 and Pond C-2 (Table 21) PNA's were not present elsewhere in surface waters at OU2, and are not considered site contaminants originating from historical waste disposal activities at OU2 (see discussion for semivolatiles in soils/sediments) Their infrequent presence in two different drainages also suggest an IHSS is not the sources for PNAs. These compounds all

Technical Memorandum 2 903 Pad Mound and East Trenches Areas Revision 1 eg&g\wp-adden\ou2-btl.sep

occurred at estimated concentrations less than or equal to $4 \mu g/L$ It is noted that the source of immobile contaminants (base neutral extractables and pesticides/PCBs) at SW-101 cannot be IHSSs associated with OU2 because those IHSSs are isolated from the South Walnut Creek drainage above Pond B-4 by the Central Avenue Ditch These contaminants do not migrate readily in ground water

In general, none of the base neutral extractable compounds would be considered contaminants of concern from a human health risk assessment perspective owing to either their infrequent occurrence, low concentrations (estimated below detection limits), likelihood as a laboratory contaminant, or general absence in soils and sediments. Further analysis for base neutral extractable compounds in surface water or ground water is not warranted during the Phase II RFI/RI

Pesticides/PCBs

As shown in Tables 22, 23, and 24, pesticide/PCBs occurrences in surface water are rare and none of these compounds have been detected in ground water. Atrazine and simazine are two herbicides that were detected in surface water (Table 25). (For convenience, herbicides that have been analyzed at the RFP are included in the pesticide/PCB group. Observed concentrations are less than 3 μ g/ ℓ which is the MCL for atrazine (Table 3). These compounds are not known to be associated with waste disposal at OU2, but rather, their occurrence in surface water reflects their probable use at the RFP in weed control. AROCLOR-1254 is the only PCB that occurred in surface water. It was present at SW-60 at a concentration of 0.15 μ g/ ℓ and was not detected in three other samplings at this location (Table 25). As discussed for the base neutral extractables, AROCHLOR-1254 at SW-60 could not have arisen from OU2 because OU2 is isolated from South Walnut Creek by the Central Avenue Ditch. Because there is no record of disposal of pesticides or PCBs at OU2, and they did not occur in ground or surface water (attributable to OU2), the elimination of pesticide/PCB analysis from future ground-water and surface water monitoring at OU2 is justified. Herbicides will be monitored in surface water via other RFP programs, as appropriate

Soils and Sediments

Volatile Organic Compounds

As shown in Tables 26 and 27, like ground water and surface water, chlorinated aliphatics occur in soils and sediments with high frequency and at high concentrations. These compounds are known waste constituents that are both toxic and mobile in the environment. These constituents should continue to be analyzed. Although the monocyclic aromatics and the ketones appear to occur at concentrations far below their acceptable concentrations, the actual concentrations in soils within IHSSs is not known. As previously discussed, this is because the sampling technique for VOCs in soils was inadequate. Elimination of monocyclic

Technical Memorandum 2 903 Pad Mound and East Trenchee Areas Revision 1 eg&g/wp-adden/ou2-brt.sep aromatics and ketones cannot be justified because the soil/sediment RI data is of little useability as a result of the sample collection issue. Therefore, the full suite of TCL volatiles will be analyzed for these media during the Phase II investigation.

Semivolatiles (acid extractables)

Out of 198 analyses for acid extractables, there are only three detections of chemicals in this class for soils/sediments at OU2 (Tables 28, 29, and 30). Pentachlorophenol was detected at estimated concentrations below the detection limit (95J μ g/t and 41J μ g/t, respectively) at boreholes BH4787 and BH5487. This compound was not detected in surface water and was detected at only a very low concentration in ground water at a downgradient well remote from these boreholes. If this compound is truly a contaminant, it is at concentrations in soils far below the health-based reference concentration, and is not migrating into water at concentrations that would present an unacceptable human health risk. Nevertheless, samples from Trenches T-5 through T-9, which are in the area where pentachlorophenol was detected (Table 9), will be analyzed for all TCL organics because these IHSSs were not previously penetrated and sampled (see below). The phenol detected at SED030 (650J μ g/t) is far below the health-based reference concentration, and if it is a contaminant, it is also not migrating into surface water at levels that would pose an unacceptable human health risk. Also, SED-30 is within the Woman Creek drainage south of the South interceptor Ditch (SiD), and is thus isolated from the OU2 IHSSs with respect to runoff

As shown in Table 31, several waste source boreholes have been proposed in IHSSs because previous drilling did not penetrate these waste sources. Therefore, these IHSSs are not chemically characterized and these waste source borehole samples will be analyzed for all TCL organics. However, other boreholes will only be analyzed for TCL volatiles

Semivolatiles (base neutral extractables)

There are frequent occurrences of base neutral extractables in soils/sediments at OU2 (Tables 32 and 33) However, phthalate esters represent the majority of these occurrences, and were present in soils throughout OU2. The presence of phthalate esters in samples is surmised to be due to field contamination from handling the samples with plastic gloves. Regardless, the concentrations of the phthalate esters are far below the health-based reference concentration for bis(2-ethylhexyl) phthalate (assumed to be representative of the class). Also, phthalates are extremely immobile in the environment. This is demonstrated by the site data that show the relatively infrequent occurrence of phthalates in water at OU2. N-nitrodiphenylamine is the next most frequently occurring base neutral extractable. However, as discussed for surface water, this is considered a laboratory contaminant (occurs at estimated concentrations and is often present in the associated laboratory blanks), and also occurs at concentrations far below the health-based reference concentration

Technical Memorandum 2 903 Pad Mound, and East Trenches Areas Revision 1 eg&g/wp-adden/ou2-bt.sep PNAs comprise the remainder of the occurrences of base neutral extractables in soils/sediments (Table 34). The PNAs occurred in only two soil samples at OU2. These samples are the 0-5 foot composites for boreholes BH3687 and BH3787. Concentrations were low occurring at estimated values below the detection limit. These boreholes are associated with the Mound Site (Table 9) where waste burning (a source for PNAs) is not known to have occurred. Because the PNAs occur in the composite sample from boreholes that includes the surface, PNAs are not likely associated with past disposal of waste at OU2. It appears that the occurrence of PNAs is a result of deposition in the environment from other sources, e.g., burning of fossil fuels, fires, etc. PNAs are also immobile in the environment which is supported by the OU2 water quality data. The low concentration of PNAs occurring at SED-12 could not have arisen from OU2 IHSSs because the IHSSs are separated from SED-12 by the Central Avenue Ditch. Therefore, only those boreholes at OU2 that will penetrate IHSSs for the first time, will be analyzed for base neutral extractables.

Pesticides/PCBs

Out of 203 analyses for pesticides/PCBs, there are only two occurrences of PCBs, and one occurrence of pesticides in soils/sediments at OU2 (Tables 35, 36, and 37). AROCHLOR-1254 occurred in one soil sample (21J μ g/kg) at the Mound Site (Table 9) at an estimated value below the detection limit. The concentration below the action level of 90 μ g/kg. AROCLOR-1254 occurred at 540 μ g/kg at SED011 along with 4,4'-DDT (95 μ g/kg). As previously discussed SED-11 is in the upper reach of South Walnut Creek which is isolated from surface water runoff from OU2. Because pesticides/PCBs are relatively immobile in ground water, these contaminants did not arise from OU2. Therefore, all sediments and boreholes that penetrate previously sampled IHSSs will not be analyzed for pesticides/PCBs. All sediment stations will be analyzed for pesticides/PCBs

CONCLUSIONS

The conclusions presented above that delineate retaining or deleting analytical suites from future monitoring of environmental media at OU2 are summarized in Table 38 and schematically presented in Figures 2 and 3. Elimination of certain analytical suites from future monitoring/characterization of the various media at this OU is well justified and will not compromise achieving the objectives of the Phase II RFI/RI. The future investigation activities will provide better characterization of the extent of contamination for those contaminants that are significant from a waste disposal and human health risk perspective. Only waste characterization within IHSSs at OU2 that were not previously investigated will include the full suite of TCL organics because of the current lack of soil/waste characterization data for these sources. If semivolatiles or pesticides/PCBs are detected at these IHSSs at significant levels, ground-water wells, surface water, and

sediment stations in the proximity of these IHSSs will be sampled and analyzed for these compounds at a later date, but prior to submittal of the Phase II RFI/RI report.

Lastly, because CLP gas chromatograph/mass spectrometer (GC/MS) detection limits do not achieve "risk based" detection limits for some of the carcinogenic chlorinated solvents, EPA Method 502 2, which has detection limits as low as $0.5 \mu g/L$, will be used for ground-water samples that are collected from wells near the edge of the plume (Table 39). This will allow achieving data quality objections for the RFI/RI. All proposed 1991 wells (alluvial and bedrock) are being installed to better define the plume of organic contamination, and, therefore, samples from these wells will be analyzed for volatiles using this method. Samples from existing wells and surface water stations remote from the IHSSs, as identified on Figures 2 and 3, will also be analyzed for volatiles using this method.
